CHAPTER 2

Semiconductor Nanomaterials**Monika Chauhan^{1,*}, Ananya Bhatia¹, Diwakar Chauhan¹ and A. K. Jain¹**¹ *Department of Chemistry, School of Basic Sciences, Galgotias University, Greater Noida, India*

Abstract: The physical and chemical characteristics of semiconductor materials radically alter as their size is shrunk to the nanoscale, giving rise to unusual traits because of their enormous surface area or quantum size effect. Despite being at the research stage right now, semiconductor nanomaterials and devices hold great promise for use in a variety of sectors, including solar cells, nanoscale electronics, light-emitting nanodevices, laser technology, waveguides, pharmaceuticals, and biosensors. The semiconductors will undoubtedly experience substantial advancements as nanotechnology continues to advance. The entire mechanism is regulated with the help of band theory, which includes valence band, conduction band and an energy gap, also considered forbidden gaps. These semiconductors when converted into nano sizes are corresponded to nanoparticles, which have the potential to accommodate various functionalities due to the reduced size, which increases the surface area for better function, adsorption, efficiency, and other things as discussed in the book chapter. This chapter also focuses on some of the most important activities now underway and problems that must be solved to enhance nanostructures and nanodevices based on semiconductors.

Keywords: Light emitting nano devices, Nanomaterials, Semiconductors, Solar cells.

INTRODUCTION

Semiconductors are substances with significant capability of conversion of their electrical properties from conductors to insulators and then to conductors. Semiconductor nanoparticles were made by various techniques to get the desired shape, size, and dimension. This is done by reducing the size of semiconductors to change their physicochemical properties to generate a quantum size effect. The entire field is so widely helpful and the most promising research for their implementations as light emitting nanodevices, laser technology, waveguide, *etc.* [1]. Majorly the conductivity and optical properties of semiconductors like

absorption coefficient and their refractive indices have been altered to induce nanomaterial properties. Various semiconductor nanomaterials such as Si, Si-Ge, AlInGaP, CdSe, CdS, *etc.* have been significantly used in various applications such as in computers, cell phones, CD players, satellites, traffic signals, *etc.* Semiconductors are usually generated from a variety of differently rated compounds of type II-VI, III-V, or IV-VI semiconductor nanocrystals as per the modern periodic table [1, 2]. Reduction of size affects the physical properties of semiconductors such as structure, appearance, magnetic properties, optical properties, dielectric properties, and various thermal properties. This is due to surface effects and quantum size effects. Hence, because of the extremely small size of these materials, they exhibit properties that are essentially different from the original form of semiconductors and become superior in their characteristics and other viable properties [3].

In nanomaterials generated from semiconductors, electrons are confined to regions having all one, two, or three-dimensional structures, when comparing their sizes and dimensions according to de Broglie's wavelength [4]. In the subsequent history of nanotechnology, Nanosciences is subsequently gaining a lot of potential and has an impact on various research fields. However, in the 21st century, there has been subsequent production in Nanosciences between a range of diameter of 1 to 20nm [4, 5]. According to various research works, nanosciences has opened new options and availability for drug delivery, and gene therapy. Nanomaterials are also used for various diagnostic codes in medical sciences and can be used as nanocapsules and nanodevices. Nanoparticles are so widely useful for investigation purposes in forensic sciences; the major predictable uses are in fingerprints, forensic chemistry, *etc.* [6]. For decades, carbon nanotubes have been so widely used due to their thermal conductivity being twice to that of even diamonds. These nanotubes generally carry an electric current 1000 times more than in a simple copper wire, and are thermally stable in a vacuum up to 2700°C. Carbon nanotubes can be reinforced into nanocomposites, and have a wider range of other possible uses such as in electronic devices, nanocomputers, transistors, solar cells, types of diodes, such as light emitting diodes (LED), silicon-controlled rectifiers, and digital and analog circuits, hydrogen production, synthesis of silicon semiconductors and their useful devices. Various other optoelectronic devices are wide examples of semiconductor devices.

Nanotechnology has been significantly integrated with a variety of other disciplines propagating its effective and continuous use. Examples of such integrated disciplines include nanosciences, nanobiotechnology, nanochemistry, nanophysics, nano-forensics, *etc.* [7, 8]. Additionally, research into nanoparticles and nanostructures is a crucial area for developing new norms, frameworks, and

methods, perhaps leading to advancements in difficult logical problems. Nanomaterials formed from nanoparticles and nanocrystals exhibit unique optical and electrical properties [9] Subsequently, these nanomaterials are classified as Zero dimensional nanomaterials, quasi-one-dimensional nanomaterials, two-dimensional nanomaterials, and three-dimensional nanomaterials. All these nanomaterials have different chemical and physical properties. These are relatively different in conductivity, resistance, and uses on the nanoscale [10].

The entire book chapter presents a thorough study of semiconductor nanomaterials, their formation, hybrids of nanomaterials, their types, functionality, and applications. [11].

NANOSCIENCES AND NANOTECHNOLOGY

Nanosciences and nanotechnology deal with the manipulation of materials at the nanoscale or nano-diameter. This manipulation has been made by scientists and nanotechnologists to make various fundamentals of life possible, to create eco-friendly and sustainable products, and to emphasize eco-friendly development [12]. Since ancient times only, various chemically synthesized nanomaterials have been significant in use. Nanomaterials in the recent world have become potentially important both to scientists, and technologists, in medical sciences and practices, diagnostic activity, drug delivery systems, *etc.* [13, 14]. These materials are evident mainly due to their physical-chemical characterization and due to these characteristics, nanomaterials open new windows towards processing of other efficient high-performance materials.

The terminology nanomaterials has been a significant part of the modest term 'nano' which is derived from the Greek word 'dwarf'. Nanomaterials have been significantly classified as nanoparticles, nanoclays, and nanoemulsions. Further classification of nanoparticles is as follows: organic nanoparticles and, inorganic nanoparticles as shown in Fig. (1) [15].

Nanoparticles have been accepted as useful materials in mega industries incorporated by nanotechnology. Nanoparticle science is a subsequent branch of substances that are dissected with various instruments and advancements in nanoparticle science. Nanomaterials made from semiconductors are crystalline with approximate sizes of 1-100nm. The majority of semiconductors are usually explained as band hole vitality, which in turn requires an electron to move from valence vitality into empty vitality bands [16]. These nanomaterials have very few electrons in their conduction band and have more electrons in the valence band. Major fields of research in nanotechnology are summarised in tabular form in Table 1 [16 - 20].
